

What Is Metamorphism?

- **Metamorphism** means to “change form”
 - The transition of one rock into another by temperatures and/or pressures unlike those in which it formed
 - Changes in mineralogy and sometimes chemical composition

© 2014 Pearson Education, Inc.

What Is Metamorphism?

- Every metamorphic rock has a **parent rock** (the rock from which it formed)
 - Parent rocks can be igneous, sedimentary, or other metamorphic rocks

© 2014 Pearson Education, Inc.

What Is Metamorphism?

- **Metamorphic grade** is the degree to which the parent rock changes during metamorphism
 - Progresses from low grade (low temperatures and pressures) to high grade (high temperatures and pressures)
 - During metamorphism, the rock must remain essentially solid

What Drives Metamorphism?

- Heat
 - Most important agent
 - **Recrystallization** is the process of forming new, stable minerals larger than the original
 - Two sources of heat:
 - Geothermal gradient: an increase in temperature with depth (about 25° C per kilometer)
 - Contact metamorphism: rising mantle plumes

© 2014 Pearson Education, Inc.

What Drives Metamorphism?

- **Confining Pressure**
 - Forces are applied equally in all directions
 - Analogous to water pressure
 - Causes the spaces between mineral grains to close

© 2014 Pearson Education, Inc.

What Drives Metamorphism?

- **Differential Stress**
 - Forces are unequal in different directions
 - Stresses are greater in one direction
 - **Compressional stress**
 - Rocks are squeezed as if in a vice
 - Shortened in one direction and elongated in the other direction

Confining Pressure and Differential Stress

© 2014 Pearson Education, Inc.

What Drives Metamorphism?

- Chemically Active Fluids
 - Enhances migration of ions
 - Aids in recrystallization of existing minerals
 - In some environments, fluids can transport mineral matter over considerable distances

© 2014 Pearson Education, Inc.

What Drives Metamorphism?

- The Importance of Parent Rock
 - Most metamorphic rocks have the same overall chemical composition as the original parent rock
 - Mineral makeup determines the degree to which each metamorphic agent will cause change

© 2014 Pearson Education, Inc.

Metamorphic Textures

- **Texture** describes the size, shape, and arrangement of mineral grains
 - Metamorphic rocks can display preferred orientation of minerals, where the platy mineral grains exhibit parallel to subparallel alignment

© 2014 Pearson Education, Inc.

Metamorphic Textures

- **Foliation** describes any planar arrangement of mineral grains or structural features within a rock
 - Examples of foliation
 - Parallel alignment of platy and/or elongated minerals
 - Parallel alignment of flattened mineral grains or pebbles
 - Compositional banding of dark and light minerals
 - Cleavage where rocks can be easily split into slabs

© 2014 Pearson Education, Inc.

Metamorphic Textures

- **Foliation**
 - Foliation can form in various ways, including:
 - Rotation of platy minerals
 - Recrystallization that produces new minerals perpendicular to the direction of maximum stress
 - Flattening spherically shaped grains

© 2014 Pearson Education, Inc.

Solid State Flow

© 2014 Pearson Education, Inc.

Metamorphic Textures

- **Foliated Textures**
 - **Rock or slaty cleavage**
 - Rocks split into thin slabs
 - Develops in beds of shale with low-grade metamorphism

© 2014 Pearson Education, Inc.

Excellent Slaty Cleavage

© 2014 Pearson Education, Inc.

Metamorphic Textures

- Foliated Textures
 - **Schistosity**
 - Platy minerals are discernible with the unaided eye
 - Mica and chlorite flakes begin to recrystallize into large muscovite and biotite crystals
 - Exhibit a planar or layered structure
 - Rocks having this texture are referred to as schist

© 2014 Pearson Education, Inc.

Metamorphic Textures

- Foliated Textures
 - **Gneissic texture**
 - During high-grade metamorphism, ion migration results in the segregation of minerals into light and dark bands
 - Metamorphic rocks with this texture are called gneiss
 - Although foliated, gneiss do not usually split as easily as slates and schists

© 2014 Pearson Education, Inc.

Metamorphic Textures

- Other Metamorphic Textures
 - **Nonfoliated** metamorphic rocks are composed of minerals that exhibit equidimensional crystals and lack foliation
 - Develop in environments where deformation is minimal
 - **Porphyroblastic textures**
 - Unusually large grains, called porphyroblasts, are surrounded by a fine-grained matrix of other minerals

Common Metamorphic Rocks

- Foliated Rocks
 - **Slate**
 - Very fine-grained
 - Excellent rock cleavage
 - Most often generated from low-grade metamorphism of shale, mudstone, or siltstone

© 2014 Pearson Education, Inc.

Common Metamorphic Rocks

- Foliated Rocks
 - **Phyllite**
 - Degree of metamorphism between slate and schist
 - Platy minerals are larger than slate but not large enough to see with the unaided eye
 - Glossy sheen and wavy surfaces
 - Exhibits rock cleavage

© 2014 Pearson Education, Inc.

Common Metamorphic Rocks

- Foliated Rocks
 - Schist
 - Medium- to coarse-grained
 - Parent rock is shale that has undergone medium- to high-grade metamorphism
 - The term *schist* describes the texture
 - Platy minerals (mainly micas) predominate
 - Can also contain porphyroblasts

© 2014 Pearson Education, Inc.

Common Metamorphic Rocks

- Foliated Rocks
 - Gneiss
 - Medium- to coarse-grained metamorphic rock with a banded appearance
 - The result of high-grade metamorphism
 - Composed of light-colored, feldspar-rich layers with bands of dark ferromagnesian minerals

© 2014 Pearson Education, Inc.

Increasing Metamorphic Grade

© 2014 Pearson Education, Inc.

Common Metamorphic Rocks

- Nonfoliated Rocks
 - Marble
 - Crystalline rock from limestone or dolostone parent rock
 - Main mineral is calcite
 - Calcite is relatively soft (3 on the Mohs scale)
 - Used as a decorative and monument stone
 - Impurities in the parent rocks provide a variety of colors

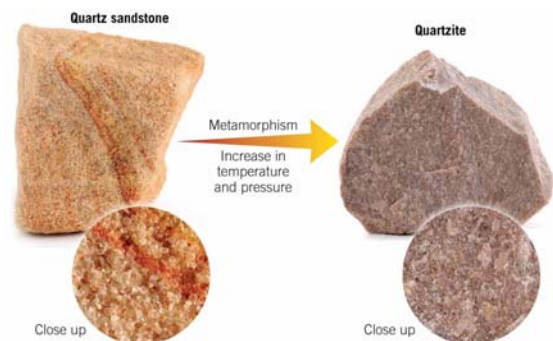

© 2014 Pearson Education, Inc.

Common Metamorphic Rocks

- Nonfoliated Rocks
 - Quartzite
 - Formed from a parent rock of quartz-rich sandstone
 - Quartz grains are fused together
 - Pure quartzite is white
 - Iron oxide may produce reddish or pink stains
 - Dark minerals may produce green or gray stains

© 2014 Pearson Education, Inc.

Quartzite

© 2014 Pearson Education, Inc.

Common Metamorphic Rocks

- Nonfoliated Rocks
 - Hornfels
 - Parent rock is shale or clay-rich rocks
 - “Baked” by an intruding magma body

© 2014 Pearson Education, Inc.

Common Metamorphic Rocks

Metamorphic Rock	Texture	Comments	Parent Rock
Slate		Composed of tiny crystals and mica fibers, tends to fall into small, sharp, cleavage, smooth slab surfaces	Shale, mudstone, or siltstone
Phyllite		Fine-grained, gray when fresh, breaks along wavy surfaces	Shale, mudstone, or siltstone
Schist		Medium to coarse grained, mica foliation, mica dominates	Shale, mudstone, or siltstone
Gneiss		Coarse grained, banded appearance, light and dark colored minerals	Shale, phyllite, or mudstone
Marble		Medium to coarse grained, crystalline, white to light gray, interlocking crystals or coarse grains	Limestone, dolomite
Quartzite		Medium to coarse grained, very hard, resistant, interlocking crystals	Quartz sandstone
Hornfels		Very fine grained, often noncrystalline, may show dark, irregularly dark colored	Other shale, but can be any rock

Metamorphic Environments

- **Contact or Thermal Metamorphism**
 - Results from a rise in temperature when magma invades a host rock
 - Occurs in the upper crust (low pressure, high temperature)
 - The zone of alteration (**aureole**) forms in the rock surrounding the magma

© 2014 Pearson Education, Inc.

Contact Metamorphism

© 2014 Pearson Education, Inc.

Metamorphic Environments

- **Hydrothermal Metamorphism**
 - Chemical alteration caused by hot, ion-rich fluids circulating through pore spaces and rock fractures
 - Typically occurs along the axes of mid-ocean ridges
 - Black smokers are the result of the fluids gushing from the seafloor

© 2014 Pearson Education, Inc.

Hydrothermal Metamorphism Along

© 2014 Pearson Education, Inc.

Metamorphic Environments

- **Burial Metamorphism**
 - Associated with very thick sedimentary strata in a subsiding basin
 - Gulf of Mexico is an example
- **Subduction Zone Metamorphism**
 - Sediments and oceanic crust are subducted fast enough that pressure increases before temperature

© 2014 Pearson Education, Inc.

Metamorphic Environments

- **Regional Metamorphism**
 - Produces the greatest quantity of metamorphic rock
 - Associated with mountain building and the collision of continental blocks

© 2014 Pearson Education, Inc.

Regional Metamorphism

© 2014 Pearson Education, Inc.

Metamorphic Environments

- **Metamorphism Along Fault Zones**
 - Occurs at depth and high temperatures
 - Preexisting minerals deform by ductile flow
 - Mylonites form in these regions of ductile deformation
- **Impact Metamorphism**
 - Occurs when meteorites strike Earth's surface
 - Product of these impacts are fused fragmented rock plus glass-rich ejecta that resemble volcanic bombs
 - Called impactites

© 2014 Pearson Education, Inc.

Metamorphism Along a Fault Zone

© 2014 Pearson Education, Inc.

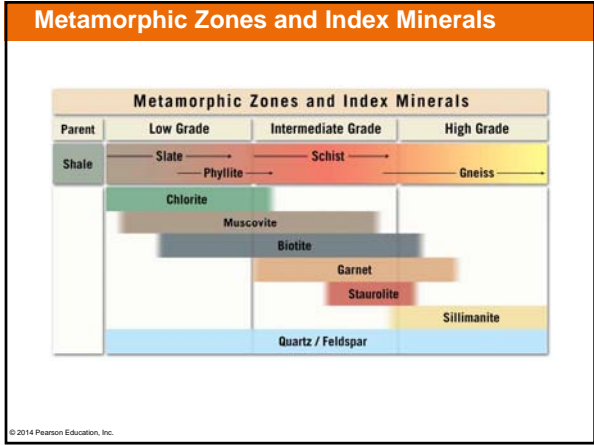

Metamorphic Zones

- **Textural Variations**
 - Slate is associated with low-grade metamorphism
 - Gneiss is associated with high-grade metamorphism
 - Phyllite and schist are intermediate

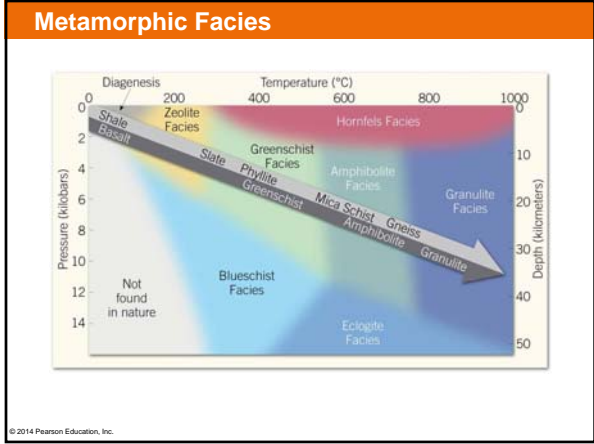

© 2014 Pearson Education, Inc.

- ### Metamorphic Zones
- Index Minerals and Metamorphic Grade
 - Changes in mineralogy occur from regions of low-grade metamorphism to regions of high-grade metamorphism
 - **Index minerals** are good indicators of metamorphic environments
 - **Migmatites** are rocks that have been partially melted
 - Represent the highest grades of metamorphism
 - Transitional to igneous rocks
- © 2014 Pearson Education, Inc.

- ### Interpreting Metamorphic Environments
- **Metamorphic Facies**
 - Metamorphic rocks that contain the same mineral assemblage and formed in similar metamorphic environments
- © 2014 Pearson Education, Inc.

- ### Interpreting Metamorphic Environments
- **Metamorphic Facies and Plate Tectonics**
 - High-pressure, low-temperature metamorphism is associated with the upper section of subduction zones
 - Regional metamorphism is associated with colliding continental blocks
 - Examples include the Appalachian Mountains
- © 2014 Pearson Education, Inc.

Interpreting Metamorphic Environments

- Mineral Stability and Metamorphic Environments
 - Some minerals are stable at certain temperature and pressure regimes
 - Examples include the polymorphs andalusite, kyanite, and sillimanite
 - Knowing the range of temperatures and pressures associated with mineral formation can aid in interpreting the metamorphic environment
